On modeling and global solutions for d.c. optimization problems by canonical duality theory

Zhong Jin · David Y Gao

Abstract This paper presents a canonical d.c. (difference of canonical and convex functions) programming problem, which can be used to model general global optimization problems in complex systems. It shows that by using the canonical duality theory, a large class of nonconvex minimization problems can be equivalently converted to a unified concave maximization problem over a convex domain, which can be solved easily under certain conditions. Additionally, a detailed proof for triality theory is provided, which can be used to identify local extremal solutions. Applications are illustrated and open problems are presented.

Keywords Global optimization · Canonical duality theory · DC programming · Mathematical modeling

1 Problems and motivation

It is known that in Euclidean space every continuous global optimization problem on a compact set can be reformulated as a d.c. optimization problem, i.e. a nonconvex problem which can be described in terms of *d.c. functions* (difference of convex functions) and *d.c. sets* (difference of convex sets) [37]. By the fact that any constraint set can be equivalently relaxed by a nonsmooth indicator function, general nonconvex optimization problems can be written in the following standard d.c. programming form

$$\min\{f(x) = g(x) - h(x) \mid \forall x \in \mathcal{X}\}, \quad (1)$$

where $\mathcal{X} = \mathbb{R}^n$, $g(x), h(x)$ are convex proper lower-semicontinuous functions on $\mathbb{R}^n$, and the d.c. function $f(x)$ to be optimized is usually called the “objective function” in mathematical optimization. A more general model is that $g(x)$ can be an arbitrary function [37]. Clearly, this d.c. programming problem is artificial. Although it can be used to “model” a very wide range of mathematical problems [24] and has been studied extensively during the last thirty years (cf. [25, 34, 39]), it comes at a price: it is impossible to have an elegant theory and powerful algorithms for solving this problem without detailed structures on these arbitrarily given functions. As the result, even some very simple d.c. programming problems are considered as NP-hard [37]. This dilemma is mainly due to the existing gap between mathematical optimization and mathematical physics.

1.1 Objectivity and multi-scale modeling

Generally speaking, the concept of *objectivity* used in our daily life means the state or quality of being true even outside of a subject’s individual biases, interpretations, feelings, and imaginings

(see Wikipedia at [https://en.wikipedia.org/wiki/Objectivity_\(philosophy\)](https://en.wikipedia.org/wiki/Objectivity_(philosophy))). In science, the objectivity is often attributed to the property of scientific measurement, as the accuracy of a measurement can be tested independent from the individual scientist who first reports it, i.e. an objective function does not depend on observers. In Lagrange mechanics and continuum physics, a real-valued function $W : \mathcal{X} \rightarrow \mathbb{R}$ is said to be objective if and only if (see [9], Chapter 6)

$$W(x) = W(Rx) \quad \forall x \in \mathcal{X}, \quad \forall R \in \mathcal{R}, \quad (2)$$

where $\mathcal{R}$ is a special rotation group such that $R^{-1} = R^T$, $\det R = 1$, $\forall R \in \mathcal{R}$.

Geometrically, an objective function does not depend on the rotation, but only on certain measure of its variable. The simplest measure in $\mathbb{R}^n$ is the ℓ_2 norm $\|x\|$, which is an objective function since $\|Rx\|^2 = (Rx)^T(Rx) = x^T R^T R x = \|x\|^2$ for all special orthogonal matrix $R \in SO(n)$. By Cholesky factorization, any positive definite matrix has a unique decomposition $C = D^* D$. Thus, any convex quadratic function is objective. It was emphasized by P.G. Ciarlet in his recent nonlinear analysis book [4] that the objectivity is not an assumption, but an axiom. Indeed, the objectivity is also known as the *axiom of frame-invariance* in continuum physics (see page 8 [27] and page 42 [35]). Although the objectivity has been well-defined in mathematical physics, it is still subjected to seriously study due to its importance in mathematical modeling (see [30, 31, 32]).

Based on the original concept of objectivity, a multi-scale mathematical model for general nonconvex systems was proposed by Gao in [9, 17]:

$$(\mathcal{P}) : \quad \inf \{ \Pi(x) = W(Dx) - F(x) \mid \forall x \in \mathcal{X} \}, \quad (3)$$

where $\mathcal{X}$ is a feasible space; $F : \mathcal{X} \rightarrow \mathbb{R} \cup \{-\infty\}$ is a so-called *subjective function*, which is linear on its effective domain $\mathcal{X}_a \subset \mathcal{X}$, wherein, certain “geometrical constraints” (such as boundary/initial conditions, etc) are given; correspondingly, $W : \mathcal{Y} \rightarrow \mathbb{R} \cup \{\infty\}$ is an *objective function* on its effective domain $\mathcal{Y}_a \subset \mathcal{Y}$, in which, certain physical constraints (such as constitutive laws, etc) are given; $D : \mathcal{X} \rightarrow \mathcal{Y}$ is a linear operator which assign each decision variable in configuration space $\mathcal{X}$ to an internal variable $y \in \mathcal{Y}$ at different scale. By Riesz representation theorem, the subjective function can be written as $F(x) = \langle x, \bar{x}^* \rangle \quad \forall x \in \mathcal{X}_a$, where $\bar{x}^* \in \mathcal{X}^*$ is a given input (or source), the bilinear form $\langle x, x^* \rangle : \mathcal{X} \times \mathcal{X}^* \rightarrow \mathbb{R}$ puts $\mathcal{X}$ and $\mathcal{X}^*$ in duality. Additionally, the positivity conditions $W(y) \geq 0 \quad \forall y \in \mathcal{Y}_a$, $F(x) \geq 0 \quad \forall x \in \mathcal{X}_a$ and coercivity condition $\lim_{\|y\| \rightarrow \infty} W(y) = \infty$ are needed for the target function $\Pi(x)$ to be bounded below on its effective domain $\mathcal{X}_c = \{x \in \mathcal{X}_a \mid Dx \in \mathcal{Y}_a\}$ [17]. Therefore, the extremality condition $0 \in \partial \Pi(x)$ leads to the equilibrium equation [9]

$$0 \in D^* \partial W(Dx) - \partial F(x) \Leftrightarrow D^* y^* - x^* = 0 \quad \forall x^* \in \partial F(x), \quad y^* \in \partial W(y). \quad (4)$$

In this model, the objective duality relation $y^* \in \partial W(y)$ is governed by the constitutive law, which depends only on mathematical modeling of the system; the subjective duality relation $x^* \in \partial F(x)$ leads to the input $\bar{x}^*$ of the system, which depends only on each given problem. Thus, $(\mathcal{P})$ can be used to model general problems in multi-scale complex systems.

1.2 Real-world problems

In management science the variable $x \in \mathcal{X}_a \subset \mathbb{R}^n$ could represent the products of a manufacture company. Its dual variable $\bar{x}^* \in \mathbb{R}^n$ can be considered as market price (or demands). Therefore, the subjective function $F(x) = x^T \bar{x}^*$ in this example is the total income of the company. The products are produced by workers $y \in \mathbb{R}^m$. Due to the cooperation, we have $y = Dx$ and $D \in \mathbb{R}^{m \times n}$ is a matrix. Workers are paid by salary $y^* = \partial W(y)$, therefore, the objective function $W(y)$ in this example is the cost. Thus, $\Pi(x) = W(Dx) - F(x)$ is the *total loss or target* and the minimization problem $(\mathcal{P})$ leads to the equilibrium equation $D^T \partial_y W(Dx) = \bar{x}^*$. The cost function $W(y)$ could be convex for a very small company, but usually nonconvex for big companies.

In Lagrange mechanics, the variable $x \in \mathcal{X} = \mathcal{C}^1[I; \mathbb{R}^n]$ is a continuous vector-valued function of time $t \in I \subset \mathbb{R}$, its components $\{x_i(t)\} (i = 1, \dots, n)$ are known as the Lagrange coordinates.

The subjective function in this case is a linear functional $F(x) = \int_I x(t)^T \bar{x}^*(t) dt$, where $\bar{x}^*(t)$ is a given external force field. While $W(Dx)$ is the so-called action:

$$W(Dx) = \int_I L(x, \dot{x}) dt, \quad L = T(\dot{x}) - V(x), \quad (5)$$

where T is the kinetic energy density, V is the potential density, and $L = T - V$ is the standard *Lagrangian density* [29]. The linear operator $Dx = \{\partial_t, 1\}x = \{\dot{x}, x\}$ is a vector-valued mapping. The kinetic energy T must be an objective function of the velocity (quadratic for Newton's mechanics and convex for Einstein's relativistic theory) [9], while the potential density V could be either convex or nonconvex, depending on each problem. Together, $\Pi(x) = W(Dx) - F(x)$ is called *total action*. The extremality condition $\partial \Pi(x) = 0$ leads to the well-known Euler-Lagrange equation

$$D^* \partial W(Dx) = \partial_t^* \frac{dT(\dot{x})}{d\dot{x}} - \frac{dV(x)}{dx} = \bar{x}^*, \quad (6)$$

where ∂_t^* is an adjoint operator of ∂_t . For convex Hamiltonian systems, both T and V are convex, thus, the least action principle leads to a typical d.c. minimization problem

$$\inf \{ \Pi(x) = K(\partial_t x) - P(x) \}, \quad K(y) = \int_I T(y) dt, \quad P(x) = \int_I [V(x) + x^T \bar{x}^*] dt, \quad (7)$$

where $K(y)$ is the kinetic energy and $P(x)$ is the total potential energy. The duality theory for this d.c. minimization problem was first studied by J. Toland [36] with successful application in nonlinear heavy rotating chain, where

$$K(y) = \int_0^1 \frac{1}{2\lambda} y^2 dt, \quad P(x) = \int_0^1 [x(t)^2 + t^2]^{1/2} dt, \quad (8)$$

and the parameter $\lambda > 0$ depends on angular speed. Clearly, in this application, $K(v)$ is quadratic while $P(x)$ is approaching to linear when $\|x(t)\|$ is sufficiently large. Therefore, the total action $\Pi(x)$ is bounded below and coercive on $\mathcal{X} = \{x(t) \in W^{1,2}[0, 1] \mid x(0) = 0\}$, the problem $(\mathcal{P})$ has a unique stable global minimizer.

However, if both $K(v)$ and $P(x)$ are quadratic functions (for example, the classical linear mass-springer system), the d.c. minimal problem $(\mathcal{P})$ will have no stable global minimizer. It was proved in [9] that, in addition to the double-min duality

$$\inf_{x \in \mathcal{X}} \{ \Pi(x) = K(\partial_t x) - P(x) \} = \inf_{y^* \in \mathcal{Y}^*} \{ \Pi^*(y^*) = P^*(\partial_t^* y^*) - K^*(y^*) \}, \quad (9)$$

the double-max duality

$$\sup_{x \in \mathcal{X}} \{ \Pi(x) = K(\partial_t x) - P(x) \} = \sup_{y^* \in \mathcal{Y}^*} \{ \Pi^*(y^*) = P^*(\partial_t^* y^*) - K^*(y^*) \} \quad (10)$$

holds alternatively, i.e. the system is in stable periodic vibration on its time domain I . Therefore, this double-min duality reveals an important truth in convex Hamiltonian systems: the least action principle is a misnomer for periodic vibration (see Chapter 2 [9]).

Now let us consider another example in buckling analysis of Euler beam:

$$\inf \{ \Pi(u) = K(\partial_{xx} u) - P(\partial_x u) \}, \quad (11)$$

where both the bending energy K and the axial strain energy P are quadratic

$$K(\partial_{xx} u) = \int_I \frac{1}{2} \alpha u_{xx}^2 dx, \quad P(\partial_x u) = \int_I \frac{1}{2} \lambda u_x^2 dx \quad (12)$$

and $\alpha > 0$ is a constant, $\lambda > 0$ is a given axial load at the end of the beam. Clearly, if $\lambda < \lambda_c$, the eigenvalue of the Euler beam defined by

$$\lambda_c = \inf \frac{\int_I \alpha u_{xx}^2 dx}{\int_I u_x^2 dx}, \quad (13)$$

the d.c. functional $\Pi(u)$ is convex and the problem $(\mathcal{P})$ has a unique solution. In this case, the Euler beam is in pre-buckling state. However, $\Pi(u)$ is concave if the axial load $\lambda > \lambda_c$ and in this case, we have $\inf \Pi(u) = -\infty$, which means that the Euler beam is collapsed. This example shows that the linear Euler beam can be used only for pre-buckling problems. Generally speaking, unconstrained quadratic d.c. programming problem does not make any physical sense unless it is convex.

In order to study the post-bifurcation problems, a nonlinear beam model was proposed by Gao [8]. Instead of quadratic function, the stored energy K in this nonlinear model is a fourth-order polynomial

$$K(\partial_{xx}u) = \int_I \left[\frac{1}{2} \alpha u_{xx}^2 + \frac{1}{12} \beta u_x^4 \right] dx, \quad (14)$$

where $\beta > 0$ is a material constant. Clearly, if $\lambda_p = \lambda - \lambda_c < 0$, $\Pi(u) = K(\partial_{xx}u) - P(\partial_x u)$ is strictly convex. In this case, the problem $(\mathcal{P})$ has a unique minimizer and the beam is in pre-buckling state. If $\lambda_p > 0$, the total potential $\Pi(u)$ is nonconvex which has two equally valued local minimizers and one local maximizer. Therefore, this nonlinear beam can be used to model post-buckling phenomena, which has been subjected to seriously study in recent years (cf. [1, 2, 26]). If the beam is subjected a lateral distributed load $q(x)$, then we have the following d.c. variational problem

$$\inf \{ \Pi(u) = W(Du) - F(u) \}, \quad (15)$$

where

$$W(Du) = \int_I \left[\frac{1}{12} \beta u_x^4 - \frac{1}{2} \lambda_p u_x^2 \right] dx, \quad F(u) = \int_I q u \, dx. \quad (16)$$

The objective function $W(Du)$ in this problem is the so-called *double-well potential*, which appears extensively in real-world problems, such as phase transitions, shape-memory alloys, chaotic dynamics and theoretical physics [11]. The subjective function $F(u)$ breaks the symmetry of this nonlinear buckling beam model and leads to one global minimizer, corresponding to a stable buckled state, one local minimizer, corresponding to one unstable buckled state, and one local maximizer, corresponding to one unbuckled state [2, 38]. By finite element method the domain I is discretized into m -elements $\{I_e\}$ such that the unknown function can be piecewisely approximated as $u(x) \simeq N_e(x)p_e$ in each element I_e with p_e as nodal variables. Then, the nonconvex variational problem (15) can be numerically reformulated to the d.c. programming problem (1) with $g(p)$ as a fourth-order polynomial and $h(p)$ a quadratic function so that $\Pi(p) = g(p) - h(p)$ is bounded below to have a global minimum solution [2, 38].

All the real-world applications discussed in this section show a simple fact, i.e. the functions $g(x)$ and $h(x)$ in the standard d.c. programming problem (1) can't be arbitrarily given, they must obey certain fundamental laws in physics in order to model real-world systems. By the facts that the subjective function $F(x) = \langle x, \bar{x}^* \rangle$ is necessary for any given real-world system in order to have non-trivial solutions (states or outputs) and the function $g(x)$ in the standard d.c. programming (1) can be generalized to a nonconvex function (see Equation (36) in [37]), it is reasonable to assume that $g(x)$ in (1) is a general nonconvex function $W(Dx)$ and $h(x)$ is a quadratic function

$$Q(x) = \frac{1}{2} \langle x, Cx \rangle + \langle x, f \rangle, \quad (17)$$

where $C : \mathcal{X} \rightarrow \mathcal{X}^*$ is a given symmetrical positive definite operator (or matrix) and $f \in \mathcal{X}^*$ is a given input. Then, the standard d.c. programming (1) can be generalized to the following form

$$(\mathcal{P}_{dc}) : \min \{ W(Dx) - Q(x) \mid \forall x \in \mathcal{X} \}. \quad (18)$$

1.3 Canonical duality theory and goal

Canonical duality-triality is a breakthrough theory which can be used not only for modeling complex systems within a unified framework, but also for solving real-world problems with a unified methodology [17]. This theory was developed originally from Gao and Strang's work

in nonconvex mechanics [21] and has been applied successfully for solving a large class of challenging problems in both nonconvex analysis/mechanics and global optimization, such as phase transitions in solids [23], post-buckling of large deformed beam [38], nonconvex polynomial minimization problems with box and integer constraints [13, 15, 18], Boolean and multiple integer programming [6, 40], fractional programming [7], mixed integer programming [20], polynomial optimization [14], high-order polynomial with log-sum-exp problem [3]. A comprehensive review on this theory and breakthrough from recent challenges are given in [19].

The goal of this paper is to apply the canonical duality theory for solving the challenging d.c. programming problem (1). The rest of this paper is arranged as follows. Based on the concept of objectivity, a canonical d.c. optimization problem and its canonical dual are formulated in the next section. Analytical solutions and triality theory for a general d.c. minimization problem with sum of nonconvex polynomial and exponential functions are discussed in Sections 3 and 4. Five special examples are illustrated in Section 5. Some conclusions and future work are given in Section 6.

2 Canonical d.c. problem and its canonical dual

It is known that the linear operator $D : \mathcal{X} \rightarrow \mathcal{Y}$ can't change the nonconvex $W(Dx)$ to a convex function. According to the definition of the objectivity, a nonconvex function $W : \mathcal{Y} \rightarrow \mathbb{R}$ is objective if and only if there exists a function $V : \mathcal{Y} \times \mathcal{Y} \rightarrow \mathbb{R}$ such that $W(y) = V(y^T y)$ [4, 17]. Based on this fact, a reasonable assumption can be made for the general problem $(\mathcal{P}_{dc})$.

Assumption 1 (Canonical Transformation and Canonical Measure)

For a given nonconvex function $W : \mathcal{Y} \rightarrow \mathbb{R} \cup \{\infty\}$, there exists a nonlinear mapping $\Lambda : \mathcal{X} \rightarrow \mathcal{E}$ and a convex, l.s.c function $V : \mathcal{E} \rightarrow \mathbb{R} \cup \{\infty\}$ such that

$$W(Dx) = V(\Lambda(x)). \quad (19)$$

The nonlinear transformation (19) is actually the *canonical transformation*, first introduced by Gao in 2000 [10], and $\xi = \Lambda(x)$ is called a *canonical measure*. The canonical measure $\xi = \Lambda(x)$ is also called the *geometrically admissible measure* in the canonical duality theory [10], which is not necessarily to be objective. But the most simple canonical measure in $\mathbb{R}^n$ is the quadratic function $\xi = x^T x$, which is clearly objective. Therefore, the canonical function can be viewed as a generalized objective function. Thus, based on Assumption 1, the generalized d.c. programming problem $(\mathcal{P}_{dc})$ can be written in a canonical d.c. minimization problem form $((\mathcal{P})$ for short):

$$(\mathcal{P}) : \min \{ \Pi(x) = V(\Lambda(x)) - Q(x) \mid x \in \mathcal{X} \}. \quad (20)$$

Since the canonical measure $\xi = \Lambda(x) \in \mathcal{E}$ is nonlinear and $V(\xi)$ is convex on $\mathcal{E}$, the composition $V(\Lambda(x))$ has a higher order nonlinearity than $Q(x)$. Therefore, the coercivity for the target function $\Pi(x)$ should be naturally satisfied, i.e.

$$\lim_{\|x\| \rightarrow \infty} \{ \Pi(x) = V(\Lambda(x)) - Q(x) \} = \infty, \quad (21)$$

which is a sufficient condition for existence of a global minimal solution to (CDC) (otherwise, the set $\mathcal{X}$ should be bounded). Clearly, this generalized d.c. minimization problem can be used to model a reasonably large class of real-world problems in mathematical physics [9, 11], global optimization [16], and computational sciences [19].

By the fact that $V(\xi)$ is convex, l.s.c. on $\mathcal{E}$, its conjugate can be uniquely defined by the Fenchel transformation

$$V^*(\xi^*) = \sup \{ \langle \xi; \xi^* \rangle - V(\xi) \mid \xi \in \mathcal{E} \}. \quad (22)$$

The bilinear form $\langle \xi; \xi^* \rangle$ puts $\mathcal{E}$ and $\mathcal{E}^*$ in duality. According to convex analysis (cf. [5]), $V^* : \mathcal{E}^* \rightarrow \mathbb{R} \cup \{+\infty\}$ is also convex, l.s.c. on its domain $\mathcal{E}^*$ and the following generalized canonical duality relations [10] hold on $\mathcal{E} \times \mathcal{E}^*$

$$\xi^* \in \partial V(\xi) \Leftrightarrow \xi \in \partial V^*(\xi^*) \Leftrightarrow V(\xi) + V^*(\xi^*) = \langle \xi; \xi^* \rangle. \quad (23)$$

Replacing $V(\Lambda(x))$ in the target function $\Pi(x)$ by the Fenchel-Young equality $V(\xi) = \langle \xi; \xi^* \rangle - V^*(\xi^*)$, Gao and Strang's total complementary function (see [10]) $\Xi : \mathcal{X} \rightarrow \mathcal{E}^* \rightarrow \mathbb{R} \cup \{-\infty\}$ for this (CDC) can be obtained as

$$\Xi(x, \xi^*) = \langle \Lambda(x); \xi^* \rangle - V^*(\xi^*) - Q(x). \quad (24)$$

By this total complementary function, the canonical dual of $\Pi(x)$ can be obtained as

$$\Pi^d(\xi^*) = \inf\{\Xi(x, \xi^*) \mid x \in \mathcal{X}\} = Q^\Lambda(\xi^*) - V^*(\xi^*), \quad (25)$$

where $Q^\Lambda : \mathcal{E}^* \rightarrow \mathbb{R} \cup \{-\infty\}$ is the so-called Λ -conjugate of $Q(x)$ defined by (see [10])

$$Q^\Lambda(\xi^*) = \inf\{\langle \Lambda(x); \xi^* \rangle - Q(x) \mid x \in \mathcal{X}\}. \quad (26)$$

If this Λ -conjugate has a non-empty effective domain, the following canonical duality

$$\inf_{x \in \mathcal{X}} \Pi(x) = \sup_{\xi^* \in \mathcal{E}^*} \Pi^d(\xi^*) \quad (27)$$

holds under certain conditions, which will be illustrated in the next section.

3 Application and analytical solution

Let us consider a special application in $\mathbb{R}^n$ such that

$$g(x) = W(Dx) = \sum_{i=1}^p \exp\left(\frac{1}{2}x^T A_i x - \alpha_i\right) + \sum_{j=1}^r \frac{1}{2} \left(\frac{1}{2}x^T B_j x - \beta_j\right)^2, \quad (28)$$

where $\{A_i\}_{i=1}^p \in \mathbb{R}^{n \times n}$ are symmetric matrices and $\{B_j\}_{j=1}^r \in \mathbb{R}^{n \times n}$ are symmetric positive definite matrices, α_i and β_j are real numbers. Clearly, $g : \mathbb{R}^n \rightarrow \mathbb{R}$ is nonconvex and highly nonlinear. This type of nonconvex function covers many real applications.

The canonical measure in this application can be given as

$$\xi = \begin{pmatrix} \theta \\ \eta \end{pmatrix} = \Lambda(x) = \begin{pmatrix} \{\frac{1}{2}x^T A_i x\}_{i=1}^p \\ \{\frac{1}{2}x^T B_j x\}_{j=1}^r \end{pmatrix} : \mathbb{R}^n \rightarrow \mathcal{E}_a \subseteq \mathbb{R}^m$$

where $m = p + r$. Therefore, a canonical function can be defined on $\mathcal{E}_a$:

$$V(\xi) = V_1(\theta) + V_2(\eta)$$

where

$$V_1(\theta) = \sum_{i=1}^p \exp(\theta_i - \alpha_i),$$

$$V_2(\eta) = \sum_{j=1}^r \frac{1}{2}(\eta_j - \beta_j)^2.$$

Here θ_i and η_j denote the i th component of θ and the j th component of η , respectively. Since $V_1(\theta)$ and $V_2(\eta)$ are convex, $V(\xi)$ is a convex function. By Legendre transformation, we have the following equation

$$V(\xi) + V^*(\zeta) = \xi^T \zeta, \quad (29)$$

where

$$\zeta = \begin{pmatrix} \tau \\ \sigma \end{pmatrix} = \begin{pmatrix} \nabla V_1(\theta) \\ \nabla V_2(\eta) \end{pmatrix} = \begin{pmatrix} \{\exp(\theta_i - \alpha_i)\}_{i=1}^p \\ \{\eta_j - \beta_j\}_{j=1}^r \end{pmatrix} : \mathcal{E}_a \rightarrow \mathcal{E}_a^* \subset \mathbb{R}^m$$

and $V^*(\zeta)$ is the conjugate function of $V(\xi)$, defined as

$$V^*(\zeta) = V_1^*(\tau) + V_2^*(\sigma) \quad (30)$$

with

$$\begin{aligned} V_1^*(\tau) &= \sum_{i=1}^p (\alpha_i + \ln(\tau_i) - 1) \tau_i, \\ V_2^*(\sigma) &= \frac{1}{2} \sigma^T \sigma + \beta^T \sigma, \end{aligned}$$

where $\beta = \{\beta_j\}$.

Since the canonical measure in this application is a quadratic operator, the total complementary function $\Xi : \mathbb{R}^n \times \mathcal{E}_a^* \rightarrow \mathbb{R}$ has the following form

$$\Xi(x, \zeta) = \frac{1}{2} x^T G(\zeta) x - f^T x - V_1^*(\tau) - V_2^*(\sigma), \quad (31)$$

where

$$G(\zeta) = \sum_{i=1}^p \tau_i A_i + \sum_{j=1}^r \sigma_j B_j - C.$$

Notice that for any given ζ , the total complementary function $\Xi(x, \zeta)$ is a quadratic function of x and its stationary points are the solutions of the following equation

$$\nabla_x \Xi(x, \zeta) = G(\zeta)x - f = 0. \quad (32)$$

If $\det(G(\zeta)) \neq 0$ for a given ζ , then (32) can be solved analytically to have a unique solution $x = G(\zeta)^{-1}f$. Let

$$\mathcal{S}_a = \{\zeta \in \mathcal{E}_a^* \mid \det(G(\zeta)) \neq 0\}. \quad (33)$$

Thus, on $\mathcal{S}_a$ the canonical dual function $\Pi^d(\zeta)$ can then be written explicitly as

$$\Pi^d(\zeta) = -\frac{1}{2} f^T G(\zeta)^{-1} f - V_1^*(\tau) - V_2^*(\sigma). \quad (34)$$

Clearly, both $\Pi^d(\zeta)$ and its domain $\mathcal{S}_a$ are nonconvex. The canonical dual problem is to find all stationary points of $\Pi^d(\zeta)$ on its domain, i.e.

$$(\mathcal{P}^d) : \quad \text{sta} \{ \Pi^d(\zeta) \mid \zeta \in \mathcal{S}_a \}. \quad (35)$$

Theorem 1 (Analytic Solution and Complementary-Dual Principle)

Problem $(\mathcal{P}^d)$ is canonical dual to the problem $(\mathcal{P})$ in the sense that if $\bar{\zeta} \in \mathcal{S}_a$ is a stationary point of $\Pi^d(\zeta)$, then

$$\bar{x} = G(\bar{\zeta})^{-1} f \quad (36)$$

is a stationary point of $\Pi(x)$, the pair $(\bar{x}, \bar{\zeta})$ is a stationary point of $\Xi(x, \zeta)$, and we have

$$\Pi(\bar{x}) = \Xi(\bar{x}, \bar{\zeta}) = \Pi^d(\bar{\zeta}). \quad (37)$$

The proof of this theorem is analogous with that in [9]. Theorem 1 shows that there is no duality gap between the primal problem $(\mathcal{P})$ and the canonical dual problem $(\mathcal{P}^d)$.

4 Triality theory

In this section we will study global optimality conditions for the critical solutions of the primal and dual problems. In order to identify both global and local extrema of both two problems, we let

$$\begin{aligned} \mathcal{S}_a^+ &= \{\zeta \in \mathcal{S}_a \mid G(\zeta) \succ 0\}, \\ \mathcal{S}_a^- &= \{\zeta \in \mathcal{S}_a \mid G(\zeta) \prec 0\}. \end{aligned}$$

where $G \succ 0$ means that G is a positive definite matrix and where $G \prec 0$ means that G is a negative definite matrix. It is easy to prove that both $\mathcal{S}_a^+$ and $\mathcal{S}_a^-$ are convex sets and

$$Q^A(\zeta) = \inf\{\langle \Lambda(x); \zeta \rangle - Q(x) \mid x \in \mathbb{R}^n\} = \begin{cases} -\frac{1}{2}f^T G(\zeta)^{-1}f & \text{if } \zeta \in \mathcal{S}_a^+ \\ -\infty & \text{otherwise} \end{cases} \quad (38)$$

This shows that $\mathcal{S}_a^+$ is an effective domain of $Q^A(\zeta)$.

For convenience, we first give the first and second derivatives of functions $\Pi(x)$ and $\Pi^d(\zeta)$:

$$\nabla \Pi(x) = G(\zeta)x - f, \quad (39)$$

$$\nabla^2 \Pi(x) = G + Z_0 H Z_0^T, \quad (40)$$

$$\nabla \Pi^d(\zeta) = \begin{pmatrix} \left\{ \frac{1}{2}f^T G^{-1} A_i G^{-1} f - \alpha_i - \ln(\tau_i) \right\}_{i=1}^p \\ \left\{ \frac{1}{2}f^T G^{-1} B_j G^{-1} f - \sigma_j - \beta_j \right\}_{j=1}^r \end{pmatrix}, \quad (41)$$

$$\nabla^2 \Pi^d(\zeta) = -Z^T G^{-1} Z - H^{-1}, \quad (42)$$

where $Z_0, Z \in \mathbb{R}^{n \times m}$ and $H \in \mathbb{R}^{m \times m}$ are defined as

$$\begin{aligned} Z_0 &= [A_1 x, \dots, A_p x, B_1 x, \dots, B_r x], \\ Z &= [A_1 G^{-1} f, \dots, A_p G^{-1} f, B_1 G^{-1} f, \dots, B_r G^{-1} f], \\ H &= \begin{bmatrix} \text{diag}(\tau) & 0 \\ 0 & E_n \end{bmatrix}, \end{aligned}$$

where E_n is a $n \times n$ identity matrix. By the fact that $\tau > 0$, the matrix H^{-1} is positive definite.

Next we can get the lemma as follows whose proof is trivial.

Lemma 1 *If $M_1, M_2, \dots, M_N \in \mathbb{R}^{n \times n}$ are symmetric positive semi-definite matrices, then $M = M_1 + M_2 + \dots + M_N$ is also a positive semi-definite matrix.*

Lemma 2 *If λ_G is an arbitrary eigenvalue of G , it follows that*

$$\lambda_G \geq \sum_{i=1}^p \tau_i \lambda_{\min}^{A_i} + \sum_{j=1}^r \sigma_j \bar{\lambda}^{B_j} - \lambda_{\max}^C,$$

in which $\lambda_{\min}^{A_i}$ is the smallest eigenvalue of A_i , $\lambda_{\max}^{C_i}$ is the largest eigenvalue of C_i , and

$$\bar{\lambda}^{B_j} = \begin{cases} \lambda_{\min}^{B_j}, & \sigma_j > 0 \\ \lambda_{\max}^{B_j}, & \sigma_j \leq 0, \end{cases} \quad (43)$$

where $\lambda_{\min}^{B_j}$ and $\lambda_{\max}^{B_j}$ are the smallest eigenvalue and the largest eigenvalue of B_j respectively.

Proof: Firstly, we need prove $\tau_i(A_i - \lambda_{\min}^{A_i} E_n)$, $\lambda_{\max}^C E_n - C$ and $\sigma_j(B_j - \bar{\lambda}^{B_j} E_n)$ are all symmetric positive semi-definite matrices.

- (a) As $\lambda_{\min}^{A_i}$ is the smallest eigenvalue of A_i , then $A_i - \lambda_{\min}^{A_i} E_n$ is symmetric positive semi-definite, so $\tau_i(A_i - \lambda_{\min}^{A_i} E_n)$ is symmetric positive semi-definite with $\tau_i = \exp(\theta_i - \alpha_i) > 0$.
- (b) As $\lambda_{\max}^C$ is the largest eigenvalue of C , then $\lambda_{\max}^C E_n - C$ is a symmetric positive semi-definite matrix.
- (c) (c.1) As $\lambda_{\min}^{B_j}$ is the smallest eigenvalue of B_j , then $B_j - \lambda_{\min}^{B_j} E_n$ is symmetric positive semi-definite, so when $\sigma_j > 0$ it holds that $\sigma_j(B_j - \lambda_{\min}^{B_j} E_n)$ is symmetric positive semi-definite.
- (c.2) As $\lambda_{\max}^{B_j}$ is the largest eigenvalue of B_j , then $B_j - \lambda_{\max}^{B_j} E_n$ is symmetric negative semi-definite, so when $\sigma_j \leq 0$ it holds that $\sigma_j(B_j - \lambda_{\max}^{B_j} E_n)$ is symmetric positive semi-definite.

From (c.1) and (c.2), we know $\sigma_j(B_j - \bar{\lambda}^{B_j} E_n)$ is always symmetric positive semi-definite.

Then by (a), (b), (c) and Lemma 1, we have

$$\sum_{i=1}^p \tau_i (A_i - \lambda_{\min}^{A_i} E_n) + \sum_{j=1}^r \sigma_j (B_j - \bar{\lambda}^{B_j} E_n) + \lambda_{\max}^C E_n - C$$

is a positive semi-definite matrix, which is equivalent to

$$G - \left(\sum_{i=1}^p \tau_i \lambda_{\min}^{A_i} + \sum_{j=1}^r \sigma_j \bar{\lambda}^{B_j} E_n - \lambda_{\max}^C \right) E_n$$

is a positive semi-definite matrix, which implies that for every eigenvalue of G , it is greater than or equal to $\sum_{i=1}^p \tau_i \lambda_{\min}^{A_i} + \sum_{j=1}^r \sigma_j \bar{\lambda}^{B_j} - \lambda_{\max}^C$. $\square$

Based on the above lemma, the following assumption is given for the establishment of solution method.

Assumption 2 *There is a critical point $\zeta = (\tau, \sigma)$ of $\Pi^d(\zeta)$, satisfying $\Delta > 0$ where*

$$\Delta = \sum_{i=1}^p \tau_i \lambda_{\min}^{A_i} + \sum_{j=1}^r \sigma_j \bar{\lambda}^{B_j} - \lambda_{\max}^C.$$

Lemma 3 *If $\bar{\zeta}$ is a stationary point of $\Pi^d(\zeta)$ satisfying Assumption 1, then $\bar{\zeta} \in \mathcal{S}_a^+$.*

Proof: From Lemma 3, we know if λ_G is an arbitrary eigenvalue of G , it holds that $\lambda_G \geq \Delta$. If $\bar{\zeta}$ is a critical point satisfying Assumption 1, then $\Delta > 0$, so for every eigenvalue of G , we have $\lambda_G \geq \Delta > 0$, then G is a positive definite matrix, i.e., $\bar{\zeta} \in \mathcal{S}_a^+$. $\square$

The following lemma is needed here. Its proof is omitted, which is similar to that of Lemma 6 in [22].

Lemma 4 *Suppose that $P \in \mathbb{R}^{n \times n}$, $U \in \mathbb{R}^{m \times m}$ and $W \in \mathbb{R}^{n \times m}$ are given symmetric matrices with*

$$P = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} \prec 0, \quad U = \begin{bmatrix} U_{11} & 0 \\ 0 & U_{22} \end{bmatrix} \succ 0, \quad \text{and } W = \begin{bmatrix} W_{11} & 0 \\ 0 & 0 \end{bmatrix},$$

where P_{11} , U_{11} and W_{11} are $r \times r$ -dimensional matrices, and W_{11} is nonsingular. Then,

$$-W^T P^{-1} W - U^{-1} \preceq 0 \Leftrightarrow P + W U W^T \preceq 0. \quad (44)$$

Now, we give the main result of this paper, triality theorem, which illustrates the relationships between the primal and canonical dual problems on global and local solutions under Assumption 1.

Theorem 2 (Triality Theorem) *Suppose that $\bar{\zeta}$ is a critical point of $\Pi^d(\zeta)$, and $\bar{x} = G(\bar{\zeta})^{-1} f$.*

1. *Min-max duality: If $\bar{\zeta}$ is the critical point satisfying Assumption 1, then the canonical min-max duality holds in the form of*

$$\Pi(\bar{x}) = \min_{x \in \mathbb{R}^n} \Pi(x) = \max_{\zeta \in \mathcal{S}_a^+} \Pi^d(\zeta) = \Pi^d(\bar{\zeta}). \quad (45)$$

2. *Double-max duality: If $\bar{\zeta} \in \mathcal{S}_a^-$, the double-max duality holds in the form that if $\bar{x}$ is a local maximizer of $\Pi(x)$ or $\bar{\zeta}$ is a local maximizer of $\Pi^d(\zeta)$, we have*

$$\Pi(\bar{x}) = \max_{x \in \mathcal{X}_0} \Pi(x) = \max_{\zeta \in \mathcal{S}_0} \Pi^d(\zeta) = \Pi^d(\bar{\zeta}) \quad (46)$$

where $\bar{x} \in \mathcal{X}_0 \subset \mathbb{R}^n$ and $\bar{\zeta} \in \mathcal{S}_0 \subset \mathcal{S}_a^-$.

3. *Double-min duality:* If $\bar{\zeta} \in \mathcal{S}_a^-$, then the double-min duality holds in the form that when $m = n$, if $\bar{x}$ is a local minimizer of $\Pi(x)$ or $\bar{\zeta}$ is a local minimizer of $\Pi^d(\zeta)$, we have

$$\Pi(\bar{x}) = \min_{x \in \mathcal{X}_0} \Pi(x) = \min_{\zeta \in \mathcal{S}_0} \Pi^d(\zeta) = \Pi^d(\bar{\zeta}) \quad (47)$$

where $\bar{x} \in \mathcal{X}_0 \subset \mathbb{R}^n$ and $\bar{\zeta} \in \mathcal{S}_0 \subset \mathcal{S}_a^-$.

Proof:

1. Because $\bar{\zeta}$ is a critical point satisfying Assumption 1, by Lemma 4 it holds $\bar{\zeta} \in \mathcal{S}_a^+$, i.e., $G(\bar{\zeta}) \succ 0$. As $G(\bar{\zeta}) \succ 0$ and $H \succ 0$, by (42) we know the Hessian of the dual function is negative definite, i.e. $\nabla^2 \Pi^d(\zeta) \prec 0$, which implies that $\Pi^d(\zeta)$ is strictly concave over $\mathcal{S}_a^+$. Hence, we get

$$\Pi^d(\bar{\zeta}) = \max_{\zeta \in \mathcal{S}_a^+} \Pi^d(\zeta). \quad (48)$$

By the convexity of $V(\xi)$, we have $V(\xi) - V(\bar{\xi}) \geq (\xi - \bar{\xi})^T \nabla V(\bar{\xi}) = (\xi - \bar{\xi})^T \bar{\zeta}$ (see [21]), so

$$V(\Lambda(x)) - V(\Lambda(\bar{x})) \geq (\Lambda(x) - \Lambda(\bar{x}))^T \bar{\zeta},$$

which implies (see page 480 [12])

$$\begin{aligned} \Pi(x) - \Pi(\bar{x}) &\geq (\Lambda(x) - \Lambda(\bar{x}))^T \bar{\zeta} - \frac{1}{2} x^T C x + \frac{1}{2} \bar{x}^T C \bar{x} - f^T(x - \bar{x}) \\ &= \frac{1}{2} (x - \bar{x})^T G(\bar{\zeta})(x - \bar{x}) + [G(\bar{\zeta})\bar{x} - f]^T(x - \bar{x}). \end{aligned} \quad (49)$$

By the facts that $G(\bar{\zeta})\bar{x} = f$ and $G(\bar{\zeta}) \succ 0$, we have $\Pi(x) \geq \Pi(\bar{x})$ for any $x \in \mathbb{R}^n$, which shows that $\bar{x}$ is a global minimizer and the equation (45) is true by Theorem 1 and (48).

2. If $\bar{\zeta}$ is a local maximizer of $\Pi^d(\zeta)$ over $\mathcal{S}_a^-$, it is true that $\nabla^2 \Pi^d(\bar{\zeta}) = -Z^T G^{-1} Z - H^{-1} \preceq 0$ and there exists a neighborhood $\mathcal{S}_0 \subset \mathcal{S}_a^-$ such that for all $\zeta \in \mathcal{S}_0$, $\nabla^2 \Pi^d(\zeta) \preceq 0$. Since the map $x = G^{-1}f$ is continuous over $\mathcal{S}_a$, the image of the map over $\mathcal{S}_0$ is a neighborhood of $\bar{x}$, which is denoted by $\mathcal{X}_0$. Now we prove that for any $x \in \mathcal{X}_0$, $\nabla^2 \Pi(x) \preceq 0$, which plus the fact that $\bar{x}$ is a critical point of $\Pi(x)$ implies $\bar{x}$ is a maximizer of $\Pi(x)$ over $\mathcal{X}_0$. By singular value decomposition, there exist orthogonal matrices $J \in \mathbb{R}^{n \times n}$, $K \in \mathbb{R}^{m \times m}$ and $R \in \mathbb{R}^{n \times m}$ with

$$R_{ij} = \begin{cases} \delta_i, & i = j \text{ and } i = 1, \dots, r, \\ 0, & \text{otherwise,} \end{cases} \quad (50)$$

where $\delta_i > 0$ for $i = 1, \dots, r$ and $r = \text{rank}(F)$, such that $ZH^{\frac{1}{2}} = JRK$, then

$$Z = JRKH^{-\frac{1}{2}}. \quad (51)$$

For any $x \in \mathcal{X}_0$, let ζ be a point satisfying $x = G^{-1}f$. Therefore, $\nabla^2 \Pi^d(\zeta) = -Z^T G^{-1} Z - H^{-1} \preceq 0$, then it holds that

$$-H^{-\frac{1}{2}} K^T R^T J^T G^{-1} J R K H^{-\frac{1}{2}} - H^{-1} \preceq 0. \quad (52)$$

Multiplying above inequality by $KH^{\frac{1}{2}}$ from the left and $H^{\frac{1}{2}} K^T$ from the right, it can be obtained that

$$-R^T J^T G^{-1} J R - E_m \preceq 0, \quad (53)$$

which, by Lemma 4, is further equivalent to

$$J^T G J + R R^T \preceq 0, \quad (54)$$

then it follows that

$$-G \succeq J R R^T J^T = J R K H^{-\frac{1}{2}} H H^{-\frac{1}{2}} K^T R^T J^T = Z H Z^T. \quad (55)$$

Thus, $\nabla^2 \Pi(x) = G + Z H Z^T \preceq 0$, then $\bar{x}$ is a maximizer of $\Pi(x)$ over $\mathcal{X}_0$.

Similarly, we can prove that if $\bar{x}$ is a maximizer of $\Pi(x)$ over $\mathcal{X}_0$, then $\bar{\zeta}$ is a maximizer of $\Pi^d(\zeta)$ over $\mathcal{S}_0$. By the Theorem 1, the equation (46) is proved.

3. Now we prove the double-min duality. Suppose that $\bar{\zeta}$ is a local minimizer of $\Pi^d(\zeta)$ in $\mathcal{S}_a^-$, then there exists a neighborhood $\mathcal{S}_0 \subset \mathcal{S}_a^-$ of $\bar{\zeta}$ such that for any $\zeta \in \mathcal{S}_0$, $\nabla^2 \Pi^d(\zeta) \succeq 0$. Let $\mathcal{X}_0$ denote the image of the map $x = G^{-1}f$ over $\mathcal{S}_0$, which is a neighborhood of $\bar{x}$. For any $x \in \mathcal{X}_0$, let ζ be a point that satisfies $x = G^{-1}f$. It follows from $\nabla^2 \Pi^d(\zeta) = -Z^T G^{-1} Z - H^{-1} \succeq 0$ that $-Z^T G^{-1} Z \succeq H^{-1} \succ 0$, which implies the matrix F is invertible. Then it is true that

$$-G^{-1} \succeq (Z^T)^{-1} H^{-1} Z^{-1}, \quad (56)$$

which is further equivalent to

$$-G \preceq Z H Z^T. \quad (57)$$

Thus, $\nabla^2 \Pi(x) = G + Z H Z^T \succeq 0$ and x is a local minimizer of $\Pi(x)$. The converse can be proved similarly. By Theorem 1, the equation (47) is then true.

The theorem is proved. $\square$

This theroem show that by the canonical min-max duality theory, the nonconvex d.c. programming problem (CDC) is equivalent to a concave maximization problem

$$(\mathcal{P}^d) : \max\{\Pi^d(\zeta) \mid \zeta \in \mathcal{S}_a^+\}, \quad (58)$$

which can be solved by well-developed deterministic methods and algorithms, say [28, 33, 39].

5 Examples

In this section, let $p = r = 1$. From the definition of (CDC) problem, A_1 is a symmetric matrix, B_1 and C_1 are two positive definite matrices. According to different cases of A_1 , following five motivating examples are provided to illustrate the proposed canonical duality method in our paper. By examining the critical points of the dual function, we will show how the dualities in the triality theory are verified by these examples.

Example 1

We consider the case that A_1 is positive definite. Let $\alpha_1 = \beta_1 = 1$ and

$$A_1 = \begin{bmatrix} 1.5 & 0 \\ 0 & 2 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 0.5 & 0 \\ 0 & 3 \end{bmatrix}, \quad C_1 = \begin{bmatrix} 1.5 & 0 \\ 0 & 1 \end{bmatrix}, \quad \text{and } f = \begin{bmatrix} 2 \\ 1 \end{bmatrix},$$

then the primal problem:

$$\min_{(x,y) \in \mathbb{R}^2} \Pi(x,y) = \exp(0.75x^2 + y^2 - 1) + 0.5(0.25x^2 + 1.5y^2 - 1)^2 - 0.75x^2 - 0.5y^2 - 2x - y.$$

The corresponding canonical dual function is

$$\Pi^d(\tau, \sigma) = -0.5 \left(\frac{4}{1.5\tau + 0.5\sigma - 1.5} + \frac{1}{2\tau + 3\sigma - 1} \right) - \tau \ln(\tau) - 0.5\sigma^2 - \sigma.$$

In this problem, $\lambda_{min}^{A_1} = 1.5$, $\lambda_{min}^{B_1} = 0.5$, $\lambda_{max}^{B_1} = 3$, and $\lambda_{max}^{C_1} = 1.5$. It is noticed that $(\bar{\tau}_1, \bar{\sigma}_1) = (2.01147, -0.223104)$ is a critical point of the dual function $\Pi^d(\tau, \sigma)$ (see Figure 1a). As $\bar{\sigma}_1 < 0$, we have $\bar{\lambda}^{B_1} = \lambda_{max}^{B_1}$ and

$$\Delta = \bar{\tau}_1 \lambda_{min}^{A_1} + \bar{\sigma}_1 \lambda_{max}^{B_1} - \lambda_{max}^{C_1} = 0.8479 > 0,$$

so Assumption 1 is satisfied, then $(\bar{\tau}_1, \bar{\sigma}_1)$ is in $\mathcal{S}_a^+$. By Theorem 1, we get $(\bar{x}_1, \bar{y}_1) = (1.42283, 0.424878)$. Moreover, we have

$$\Pi(\bar{x}_1, \bar{y}_1) = \Pi^d(\bar{\tau}_1, \bar{\sigma}_1) = -2.8428,$$

so there is no duality gap, then $(\bar{x}_1, \bar{y}_1)$ is the global solution of the primal problem, which demonstrates the min-max duality (see Figure 1).

Example 2

We consider the case that A_1 is positive semi-definite. Let $\alpha_1 = \beta_1 = 2$ and

$$A_1 = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \quad C_1 = \begin{bmatrix} 1 & 0 \\ 0 & 3 \end{bmatrix}, \quad \text{and } f = \begin{bmatrix} 2 \\ 2 \end{bmatrix},$$

then the primal problem:

$$\min_{(x,y) \in \mathbb{R}^2} \Pi(x,y) = \exp(0.5x^2 - 2) + 0.5(x^2 + 0.5y^2 - 2)^2 - 0.5x^2 - 1.5y^2 - 2x - 2y.$$

The corresponding canonical dual function is

$$\Pi^d(\tau, \sigma) = -0.5 \left(\frac{4}{\tau + 2\sigma - 1} + \frac{4}{\sigma - 3} \right) - \tau \ln(\tau) - \tau - 0.5\sigma^2 - 2\sigma.$$

In this problem, $\lambda_{min}^{A_1} = 0$, $\lambda_{min}^{B_1} = 1$, $\lambda_{max}^{B_1} = 2$, and $\lambda_{max}^{C_1} = 3$. It is noticed that $(\bar{\tau}_1, \bar{\sigma}_1) = (0.142222, 3.60283)$ is a critical point of the dual function $\Pi^d(\tau, \sigma)$ (see Figure 2a). As $\bar{\sigma}_1 > 0$, we have $\bar{\lambda}^{B_1} = \lambda_{min}^{B_1}$ and

$$\Delta = \bar{\tau}_1 \lambda_{min}^{A_1} + \bar{\sigma}_1 \lambda_{min}^{B_1} - \lambda_{max}^{C_1} = 0.60283 > 0,$$

so Assumption 1 is satisfied, then $(\bar{\tau}_1, \bar{\sigma}_1)$ is in $\mathcal{S}_a^+$. By Theorem 1, we get $(\bar{x}_1, \bar{y}_1) = (0.315066, 3.3177)$. Moreover, we have

$$\Pi(\bar{x}_1, \bar{y}_1) = \Pi^d(\bar{\tau}_1, \bar{\sigma}_1) = -17.1934,$$

so there is no duality gap, then $(\bar{x}_1, \bar{y}_1)$ is the global solution of the primal problem, which demonstrates the min-max duality (see Figure 2).

For showing the double-max duality of Example 2, we find a local maximum point of $\Pi^d(\tau, \sigma)$ in $\mathcal{S}_a^-$: $(\bar{\tau}_2, \bar{\sigma}_2) = (0.151452, -1.68381)$. By Theorem 1, we get $(\bar{x}_2, \bar{y}_2) = (-0.474364, -0.427002)$. Moreover, we have

$$\Pi(\bar{x}_2, \bar{y}_2) = \Pi^d(\bar{\tau}_2, \bar{\sigma}_2) = 2.98579,$$

and $(\bar{x}_2, \bar{y}_2)$ is also a local maximum point of $\Pi(x, y)$, which demonstrates the double-max duality (see Figure 3).

Example 3

We consider the case that A_1 is negative definite. Let $\alpha_1 = -4$, $\beta_2 = 0.5$ and

$$A_1 = \begin{bmatrix} -1 & 0 \\ 0 & -1.5 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \quad C_1 = \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix}, \quad \text{and } f = \begin{bmatrix} 5 \\ 2 \end{bmatrix},$$

then the primal problem:

$$\min_{(x,y) \in \mathbb{R}^2} \Pi(x,y) = \exp(-0.5x^2 - 0.75y^2 + 4) + 0.5(x^2 + 0.5y^2 - 0.5)^2 - x^2 - 1.5y^2 - 5x - 2y.$$

The corresponding canonical dual function is

$$\Pi^d(\tau, \sigma) = -0.5 \left(\frac{25}{-\tau + 2\sigma - 2} + \frac{4}{-1.5\tau + \sigma - 3} \right) - \tau \ln(\tau) + 5\tau - 0.5\sigma^2 - 0.5\sigma.$$

In this problem, $\lambda_{min}^{A_1} = -1.5$, $\lambda_{min}^{B_1} = 1$, $\lambda_{max}^{B_1} = 2$, and $\lambda_{max}^{C_1} = 3$. It is noticed that $(\bar{\tau}_1, \bar{\sigma}_1) = (0.145563, 3.95352)$ is a critical point of the dual function $\Pi^d(\tau, \sigma)$ (see Figure 4a). As $\bar{\sigma}_1 > 0$, we have $\bar{\lambda}^{B_1} = \lambda_{min}^{B_1}$ and

$$\Delta = \bar{\tau}_1 \lambda_{min}^{A_1} + \bar{\sigma}_1 \lambda_{min}^{B_1} - \lambda_{max}^{C_1} = 0.7352 > 0,$$

so Assumption 1 is satisfied, then $(\bar{\tau}_1, \bar{\sigma}_1)$ is in $\mathcal{S}_a^+$. By Theorem 1, we get $(\bar{x}_1, \bar{y}_1) = (0.867833, 2.72044)$. Moreover, we have

$$\Pi(\bar{x}_1, \bar{y}_1) = \Pi^d(\bar{\tau}_1, \bar{\sigma}_1) = -13.6736,$$

so there is no duality gap, then $(\bar{x}_1, \bar{y}_1)$ is the global solution of the primal problem, which demonstrates the min-max duality(see Figure 4).

For showing the double-max duality of Example 3, we find a local maximum point of $\Pi^d(\tau, \sigma)$ in S_a^- : $(\bar{\tau}_2, \bar{\sigma}_2) = (54.3685, -0.492123)$. By Theorem 1, we get $(\bar{x}_2, \bar{y}_2) = (-0.0871798, -0.023517)$. Moreover, we have

$$\Pi(\bar{x}_2, \bar{y}_2) = \Pi^d(\bar{\tau}_2, \bar{\sigma}_2) = 54.9641,$$

and $(\bar{x}_2, \bar{y}_2)$ is also a local maximum point of $\Pi(x, y)$, which demonstrates the double-max duality(see Figure 5).

Example 4

We also consider the case that A_1 is indefinite. Let $\alpha_1 = 1$, $\beta_1 = 2$ and

$$A_1 = \begin{bmatrix} -3 & 0 \\ 0 & 1 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad C_1 = \begin{bmatrix} 4 & 0 \\ 0 & 4.4 \end{bmatrix}, \quad \text{and } f = \begin{bmatrix} 1 \\ 1 \end{bmatrix},$$

then the primal problem:

$$\min_{(x,y) \in \mathbb{R}^2} \Pi(x, y) = \exp(-1.5x^2 + 0.5y^2 - 1) + 0.5(0.5x^2 + 0.5y^2 - 2)^2 - 2x^2 - 2.2y^2 - x - y.$$

The corresponding canonical dual function is

$$\Pi^d(\tau, \sigma) = -0.5 \left(\frac{1}{-3\tau + \sigma - 4} + \frac{1}{\tau + \sigma - 4.4} \right) - \tau \ln(\tau) - 0.5\sigma^2 - 2\sigma.$$

In this problem, $\lambda_{min}^{A_1} = -3$, $\lambda_{min}^{B_1} = \lambda_{max}^{B_1} = 1$, and $\lambda_{max}^{C_1} = 4.4$. It is noticed that $(\bar{\tau}_1, \bar{\sigma}_1) = (0.0612941, 4.67004)$ is a critical point of the dual function $\Pi^d(\tau, \sigma)$ (see Figure 6a). As $\bar{\sigma}_1 > 0$, we have $\bar{\lambda}^{B_1} = \lambda_{min}^{B_1}$ and

$$\Delta = \bar{\tau}_1 \lambda_{min}^{A_1} + \bar{\sigma}_1 \lambda_{min}^{B_1} - \lambda_{max}^{C_1} = 0.0862 > 0,$$

so Assumption 1 is satisfied, then $(\bar{\tau}_1, \bar{\sigma}_1)$ is in $\mathcal{S}_a^+$. By Theorem 1, we get $(\bar{x}_1, \bar{y}_1) = (2.05695, 3.01812)$. Moreover, we have

$$\Pi(\bar{x}_1, \bar{y}_1) = \Pi^d(\bar{\tau}_1, \bar{\sigma}_1) = -22.6111,$$

so there is no duality gap, then $(\bar{x}_1, \bar{y}_1)$ is the global solution of the primal problem, which demonstrates the min-max duality(see Figure 6).

For showing the double-max duality of Example 4, we find a local maximum point of $\Pi^d(\tau, \sigma)$ in S_a^- : $(\bar{\tau}_2, \bar{\sigma}_2) = (0.361948, -1.97615)$. By Theorem 1, we get $(\bar{x}_2, \bar{y}_2) = (-0.141603, -0.166273)$. Moreover, we have

$$\Pi(\bar{x}_2, \bar{y}_2) = \Pi^d(\bar{\tau}_2, \bar{\sigma}_2) = 2.52149,$$

and $(\bar{x}_2, \bar{y}_2)$ is also a local maximum point of $\Pi(x, y)$, which demonstrates the double-max duality(see Figure 7).

For showing the double-min duality of Example 4, we find a local minimum point of $\Pi^d(\tau, \sigma)$ in S_a^- : $(\bar{\tau}_3, \bar{\sigma}_3) = (0.149286, 3.90584)$. By Theorem 1, we get $(\bar{x}_3, \bar{y}_3) = (-1.84496, -2.89962)$. Moreover, we have

$$\Pi(\bar{x}_3, \bar{y}_3) = \Pi^d(\bar{\tau}_3, \bar{\sigma}_3) = -12.7833,$$

and $(\bar{x}_3, \bar{y}_3)$ is also a local minimum point of $\Pi(x, y)$, which demonstrates the double-min duality(see Figure 8).

From above double-min duality in Example 4, we can find our proposed canonical dual method can avoids a local minimum point $(\bar{x}_3, \bar{y}_3)$ of the primal problem. In fact, by the canonical dual method, the global solution is obtained, so any local minimum point is avoided. For instance, the point $(0.534285, -2.83131)$ is a local minimum point of the primal problem in Example 2 (see Figure 9a), and the local minimum value is -4.78671, but our proposed canonical dual method obtains the global minimum value -17.1934; the point $(1.29672, -2.09209)$ is a local minimum point of the primal problem in Example 3 (see Figure 9b), and the minimum value is -3.98411, but our proposed canonical dual method obtains the global minimum value -13.6736.

6 Conclusions and further work

Based on the original definition of objectivity in continuum physics, a canonical d.c. optimization problem is proposed, which can be used to model general nonconvex optimization problems in complex systems. Detailed application is provided by solving a challenging problem in $\mathbb{R}^n$. By the canonical duality theory, this nonconvex problem is able to reformulated as a concave maximization dual problem in a convex domain. A detailed proof for the triality theory is provided under a reasonable assumption. This theory can be used to identify both global and local extrema, and to develop a powerful algorithm for solving this general d.c. optimization problem. Several examples are given to illustrate detailed situations. All these examples support the Assumption 2. However, we should emphasize that this assumption is only a sufficient condition for the existence of a canonical dual solution in S_a^+ . How to relax this assumption and to obtain a necessary condition for $S_a^+ \neq \emptyset$ are still open questions. We believe that this condition should be directly related to the coercivity condition (21) of the target function $\Pi(x)$ and deserves detailed study in the future.
